1. OBJECTIVES

- Gather information on the agronomic performance of new potato genotypes.
- Collect information on external and internal tuber quality of new potato genotypes.

2. METHODOLOGY

2.1. Sites and plant material description

The trials took place in Ste-Croix near Quebec City and Lanoraie, in Lanaudiere. The plots were established in a sandy loam soil for both sites.

The trial included four (4) potato clones and varieties from Fredericton and Lethbridge research stations of Agriculture and Agri-Food Canada (AAFC), fifteen (15) from the Quebec Potato Research Consortium program, eleven (11) genotypes from the Progest 2001 breeding program and twelve (12) clones and varieties from various additional national and international programs. The varieties and clones were divided in five (5) sub-trials. The five categories were: white round, yellow flesh, long, red skin and specialties. Known varieties (14), chosen for their special characteristics, were used as controls for each category (identified as (C) in Table I).

Clones and varieties included in this trial were chosen for various reasons. Most of QP clones were chosen for their multiple resistances (nematodes, PVY and late blight), while the majority of AG clones were selected to meet the growing consumer's demand for specialties potatoes. We also found a good selection of yellow flesh and red potatoes, also a market trend.

With the control varieties, a total of 61 genotypes were tested in this trial. A list of all the genotypes evaluated is presented at Table I.

Table I. List of genotypes evaluated in each category

2.2. Experimental design

The experiment was conducted in a randomized complete block design with three replications. Plots with an area of 4.12 m² consisted of one row of 4.5 m spaced at 0.915 m.

2.3. Cultural operations

Plantation in Ste-Croix was done on May 19th and in Lanoraie on May 17th. Rows were opened and fertilizer was applied using agricultural equipment. In Ste-Croix, 160 units of nitrogen, 160 units of phosphorus and 133 units of potassium was applied and in Lanoraie 204 N, 75 P and 245 K was incorporated. Potato tubers were hand planted at every 30 cm with a ruler (Figure 1). Rows were closed mechanically with disks after a simultaneous spraying of an insecticide and a fungicide on the tubers. The harvesting of experimental plots was done using a tractor and a one row harvester (Checchi & Magli SP 50V) on September 20th in Lanoraie and September 22nd in Ste-Croix (Figure 2).

There was no irrigation at either site (Sainte-Croix and Lanoraie).

All agricultural operations performed on experimental plots were conducted similarly to what is done by commercial growers.

Figure 1. Plantation in Ste-Croix

Figure 2. Harvest in Ste-Croix

2.4. Measured parameters

Throughout the season, plant development was monitored. This included emergence, plant growth, flowering and senescence.

In the post-harvest evaluation, tubers were sized, using a potato-grading machine, into five size categories (Figure 3):

- Creamer: less than 1 ½ in. (38 mm)
- Small: 1 ½ in. to 2 ¼ in. (57 mm)
- Canada No. 1: 2 ¼ in. to 2 ¾ in. (70 mm)
- Chef: 2 ¾ in. to 4 ½ in. (114 mm)
- Jumbo: greater than 4 ½ in

Tubers normally rejected by the industry (green, misshapen, cracked and rotten) were removed manually. The quantity and weight of the rejected tubers were recorded.

For external quality, the index of rhizoctonia and scab was determined using the same evaluation key used by the Canadian Food Inspection Agency (CFIA) (Figure 4). This key includes five categories based on the percentage of disease coverage, 0 (0%) 1 (1%), 2 (1-5%), 3 (5-10%) and 4 (> 10%). For each plot, ten medium-sized tubers were randomly selected and used to determine the index of rhizoctonia and scab. Internal quality, including hollow heart, brown center, as well as vascular ring discoloration, was examined by cutting open a sample of 10 randomly selected tubers.

The appearance and uniformity of the tubers were scored according to predefined scales. For appearance, a rating from 1 to 9 was given, 1 corresponding to very unattractive potatoes and 9 to very attractive potatoes. As for uniformity, it was evaluated using a scale of 1 to 5, with 1 for tubers showing very little uniformity and 5 very uniform.

The specific gravity of all potato plots was measured (Figure 5). To do this, a sample of potatoes was weighed in air and noted. Then, the same sample was weighed in water and noted. The specific gravity was then calculated according to the following formula: weight in air / (weight in air – weight in water).

Statistic analysis, using Statistix 10.0 program, was used for the yield, as well as the internal and external quality for the two sites.

Figure 3. Potato grading

Figure 4. External and internal quality evaluation

Figure 5. Specific gravity evaluation

3. RESULTS

3.1. White round potatoes

3.1.1. Ste-Croix

- Between all the different genotypes, there is no significant difference regarding the total yield (Table II).
- Only Nougat, QP12056.16 and FV16324-08 did not generate tubers with vascular ring among all genotypes (Table III).
- All genotypes had a specific gravity higher than 1,080.

Data are the means of three replications (one row/replication)

Data followed by a different letter in the same column are significantly different ($P < 0.05$) according to the Tukey test

3.1.2. Lanoraie

- For all genotypes, yields are considerably lower in Lanoraie compared to Ste-Croix mostly due to the lack of irrigation in a sandy soil during a season with high temperatures and drought periods (Table IV).
- Except FV16324-08 and Superior (C), all genotypes were significantly less affected by vascular ring disorder than Snowden (C).
- Alliston generated an important amount of downgraded tubers (9% of its total yield), mostly because of growth cracks and tuber malformation (Table V).
- The analysis of specific gravity was not possible for the following clones and cultivars (Envol (C), Mystère (C), QP13099.04, FV16324-08, Nougat, Snowden (C) and Superior (C)) because of their extremely low yield (Table V).

Table IV. Yield of genotypes in the “white round potatoes” category in Lanoraie

3.2. Yellow flesh potatoes

3.2.1. Ste-Croix

- Belmonda, Connect and 401-1 generated a significantly higher yield than 2 controls (Yukon gold and Keuka Gold) while being similar to the third control Vivaldi (Table VI).
- All genotypes produced the most tubers in Canada N° 1 grade.
- The specific gravity of the cultivar Belmonda (1,100) is significantly higher than all other genotypes. The cultivar Obama have a specific gravity (1,074) significantly lower in comparison to the other genotypes (Table VII).

3.2.2. Lanoraie

- For all genotypes, yields are considerably lower in Lanoraie compared to Ste-Croix (Table VIII).
- Connect generated significantly more downgraded tubers (11% of the total yield) than all other lines apart from Yukon gold (C). These downgraded tubers are mostly malformed.
- The cultivar Connect has a significantly higher percentage of tuber with vascular ring (Table VIII).
- Globally, the external and internal qualities were good for yellow genotypes in Lanoraie.
- For clone QP12081.11 low yield limited its specific gravity analysis.
- Yukon Gold (C) and QP12081.11 have a significant lower appearance grade than all other genotypes except Connect.

3.3. Long potatoes

3.3.1. Ste-Croix

- All genotypes except Rickey and AG1424.11 have significantly less Downgraded tubers compared to the control Goldrush. Most of Goldrush downgraded tubers were malformed (Table X).

- All genotypes had a significantly lower rhizoctonia index than the control Goldrush (Table XI)
- Mostly intended for the processing market, the long-shaped potatoes should present a high specific gravity. Results show that 8 genotypes generated a high specific gravity (≥ 1.086). VF14016 has a significant higher specific gravity (1.103).

Table X. Yield of genotypes in the “long potatoes” category in Ste-Croix

3.3.2. Lanoriae

- Yields from all genotypes were lower in Lanoriae as compared to Sainte-Croix (Table XII).
- Rickey and QP13116.15 generated a significant higher yield compared to all controls and other genotypes.
- These two genotypes also generated significantly more downgraded tubers with respectively 33% and 15% of their total yield downgraded for QP13116.15 and Rickey.
- The clone QP13094.03 also generated a high percentage (24%) of downgraded tubers mostly from growth cracks.
- VF14016 generated a high percentage of tubers with vascular ring (20%) (Table XIII).
- Excepting the previous example regarding VF14016, internal and external qualities of the other genotypes were good.
- The analysis of specific gravity was not possible for the following clones et cultivars (AG1424.11, QP12115.03, Goldrush (C), QP13094.03, VF14016, Clearwater and F14021) because of their extremely low yield.

3.4. Red skin potatoes

3.4.1. Ste-Croix

- All genotypes had significantly less downgraded tubers compared to the control Viking for which 28% of its total yield was downgraded mostly because of growth cracks (Table XIV).
- Eight (8) genotypes (Rosi, AG1533, Elmo, AG1534, QP12058.62, AG1540, AH1404.09 and QP12058.36) generated a higher yield in comparison to the 4 controls (no significant differences).
- AG1535 clone has a significantly higher rhizoctonia index than all other genotypes (Table XV).

Table XIV. Yield of genotypes in the “red skin potatoes” category in Ste-Croix

Genotype	Total (cwt/a)	Creamer <1½ " (cwt/a)	Small 1½-2¼ " (cwt/a)	Canada No 1 2¼-2¾ " (cwt/a)	Chef 2¾-4½ " (cwt/a)	Downgraded (cwt/a)

Data followed by a different letter in the same column are significantly different ($P < 0.05$) according to the Tukey test

3.5.2. Lanoriae

- Roselys (C) has significantly more downgraded tubers with 27% of its total, mostly because of growth cracks (Table XX).
- AG1405.15 and Ciklamen generated significantly lower yields than the control Roselys.
- Cyclamen had a high percentage (23,3%) of tubers with vascular ring (Table XXI).
- The analysis of specific gravity was not possible for Marispeer, Ciklamen and AG1405.15 because of their extremely low yields.

Table XX. Yield of genotypes in the “specialties potatoes” category in Lanoraie

Genotype	Total (cwt/a)	Creamer <1½ " (cwt/a)	Small 1½-2¼ " (cwt/a)	Canada No 1 2¼-2¾ " (cwt/a)	Chef 2¾-4½ " (cwt/a)	Downgraded (cwt/a)
Roselys (C)	115,2 a	4,9 c	33,1 ab	35,5 ab	10,7 a	31,0 a

Ciklamen	0,0 a	0,0 a	23,3 a	0,0000 a	0,0 a	4,7 a	2,7 a	
AG1405.15	0,0 a	0,0 a	0,0 a	0,0000 a	0,0 a	4,3 a	3,7 a	

Data are the means of three replications (one row/replication)

Data followed by a different letter in the same column are significantly different ($P < 0.05$) according to the Tukey test

4. RESULTS INTERPRETATION

- Total yields for the genotypes evaluated in Lanoriae were lower than Ste-Croix, probably due to the combination of high temperature and the lack of irrigation in a sandy soil.
- Tubers for the majority of the genotypes were more affected by vascular ring and scab in Sainte-Croix.
- Several genotypes presented a good potential regarding yield and the quality, in both category and each site. Pictures of the potential genotypes along with the control varieties are shown in the next pages.
